Season 9.5, PC ranked, balance regime 7 August to 11 September 2026. Development snapshot frozen 2026-09-09.
Report build 1303b879.

This report estimates one penalized match-level model of the probability that side 0 wins, conditional on the recorded starting lineups and pre-match information, and derives every reported quantity from that single fit. It replaces separate treatment of designated team-ups, rank bands, and pairwise interactions with one specification in which hero effects, composition effects, hero-by-map deviations, allied pairs, and opposing pairs are estimated jointly, each with a pooled rank slope, under five ridge penalties tuned on chronological development folds. The estimand is an adjusted starting-lineup association: what happens after a team starts a hero, including whatever swaps and responses follow, in the sampled competitive environment. It is not the effect of a hero’s abilities in uninterrupted play, and starting attribution alone does not make it a causal estimate.

Sample, regime, and protocol

The development snapshot holds 477,483 competitive PC ranked matches played between 2026-08-07 11:12 and 2026-09-08 11:00 UTC, after the published filters (twelve players, six per side, no draws, scores present, every player with positive play time, at least 240 seconds). The starting record must also be legal: 6,475 matches in which two teammates share the same first-appearance hero are excluded, because a shared start cannot be simultaneous and the record is unverifiable. That leaves 471,008 matches. The official patch record places the whole snapshot inside one balance regime, from the Season 9.5 patch of 7 August to the Season 10 patch of 11 September; the five intermediate updates were cosmetic. A weekly win-rate check flags only The Hood, released on 7 August, whose drift is a learning curve rather than a patch signature.

Collection was stopped at the user’s instruction, so the locked confirmation sample is internal: the 19,804 matches played in the final four days of the snapshot, after 2026-09-04 11:00 UTC. The remaining 451,204 development matches feed every design build, fold, tuning run, and table below. The confirmation outcomes are read once, after the candidate is locked, against a predeclared criterion. Because the published headline model was estimated on the whole snapshot, the baseline for that comparison is the identical headline specification refitted on the development rows.

Lobby rank, the mean pre-match score of the twelve starters, runs from 4,141 at the 5th percentile to 4,944 at the 95th, with a median of 4,548. Rank-dependent quantities are evaluated inside that range and no claim is made above 5,200. 14,722 matches have a lobby mean above 5,000, and no individual player in the sample scores above 5,750, so the top of the ranked ladder is outside the data. That is direct coverage evidence.

Specification

Let A_{mh} and B_{mh} indicate whether hero h starts on side 0 or side 1 of match m , r_m the standardized lobby rank, ΔR_m the standardized difference in team mean pre-match score, v_m the map, and $c(\cdot)$ the composition (Tank–Damage–Support counts). With $x_{mh} = A_{mh} - B_{mh}$, $z_{mhk} = A_{mh}A_{mk} - B_{mh}B_{mk}$

and $w_{mhh} = A_{mh}B_{mk} - A_{mk}B_{mh}$ for $h < k$,

$$\begin{aligned} \text{logit } p_m = & \alpha_{v_m} + (\theta_0 + \theta_1 r_m) \Delta R_m + (\gamma_0 + \gamma_1 r_m)^\top [c(A_m) - c(B_m)] + \sum_h (\beta_h + d_h r_m + u_{h,v_m}) x_{mh} \\ & + \sum_{h < k} (S_{hk} + T_{hk} r_m) z_{mhk} + \sum_{h < k} (C_{hk} + D_{hk} r_m) w_{mhk}. \end{aligned}$$

Every block uses the same starting record. The allied block is symmetric and the opposing block antisymmetric, so swapping the two camps negates every feature except the map intercept, which the implementation checks numerically. Every observed composition shape receives its own coefficient, every observed allied and opposing pair its own coefficient, and every hero its own deviation on every map; nothing is removed by a frequency threshold. The blocks are then aliased with each other in known ways: summing a hero's allied features over its five teammates gives five times its own contrast, summing its opposing features over six opponents gives six times it, summing allied features within a role pair gives a function of the composition contrast, and summing hero-by-map deviations over maps gives the hero contrast again. Each candidate centering direction was tested against the data and imposed only when its image lies exactly in the span of the lower-order blocks; 187 of 187 candidates did, with the largest residual at $7.4\text{e-}15$. The reduced design has 6,700 free coefficients.

Five ridge groups shrink the coefficients on their native scale: hero and composition averages (λ_1), allied averages (λ_2), opposing averages (λ_3), hero rank slopes, composition rank slopes and hero-by-map deviations (λ_4), and pair rank slopes (λ_5). Map intercepts and the two rank-imbalance terms are unpenalized. The rank basis and ΔR are scaled with training rows only. Designated team-ups are labels attached after estimation; they receive no separate regressors, constraints, or penalties.

Tuning

Penalties were tuned on three chronological development folds, training on the first 60, 73 and 87 per cent of development matches by play time and validating on the following slice of about 60,000 matches each. A bounded coordinate search on $\log_{10} \lambda$ with warm starts ran 39 evaluations. The selected penalties are $\lambda = (10, 900, 1000, 1000, 30000)$, with mean validation log loss 0.66809 and mean calibration slope 1.002, against 0.67012 for the refitted headline specification on the same folds, a gain of +0.00204. Calibration by supported rank third is 0.984, 1.022, and 0.997.

Table 1: Best evaluations of the penalty search (lowest validation log loss first)

$\lambda_1, \lambda_2, \lambda_3, \lambda_4, \lambda_5$	Mean validation log loss	Mean calibration slope	Converged
10,900,1000,1000,30000	0.66809	1.002	yes
3.33333,900,1000,1000,30000	0.66809	1.000	yes
30,900,1000,1000,30000	0.66809	1.004	yes
10,900,1000,1000,90000	0.66809	1.002	yes
10,900,1000,1000,1e+09	0.66809	1.002	yes
10,900,1000,1000,10000	0.66811	0.999	yes
10,900,1000,3000,30000	0.66814	1.010	yes
10,900,1000,3000,90000	0.66814	1.010	yes

Table 2: Development ladder: genuine reduced fits at the selected penalties

Model	Free parameters	Fold 1	Fold 2	Fold 3	Mean	Cal. slope
Headline specification, refitted on development rows	187	0.67059	0.67082	0.66896	0.67012	—
Heroes, composition, maps, rank imbalance	96	0.67230	0.67197	0.67030	0.67152	1.009
+ rank slopes and hero-by-map	984	0.67159	0.67118	0.66964	0.67080	1.001
+ allied and opposing pairs (no pair slopes)	3,842	0.66924	0.66814	0.66690	0.66809	1.002
+ pair rank slopes (selected fit)	6,700	0.66923	0.66814	0.66689	0.66809	1.002

Notes. Validation log loss on the same three chronological folds. Reduced fits set the omitted blocks’ penalties to 10^9 , which drives those coefficients to zero, so each row is a genuine reduced model rather than a post-hoc zeroing. The headline row is the published specification (187 parameters, starting-hero attribution, within-role constraint, map intercepts, designated team-ups) refitted on the development rows.

Hero values

Table 3 reports three things per hero from the selected fit. The coefficient β_h is the within-role log-odds contrast at the median lobby rank, reported with its slope per standard deviation of rank, so a reader can place it anywhere in the supported range. The replacement scores are exact predicted probability differences, in percentage points, from placing the hero into a starting slot in place of another hero of the same role, recomputing all five allied and six opposing relationships, the hero-by-map deviation, and the rank slope, and keeping the slot’s player, rank, map, side, and the other eleven starters fixed. Two references are declared. The observed-meta score replaces the hero that actually started in the slot, averaged over 120,000 development matches. The common-reference score compares the hero with the average legal same-role hero in the same slot, so every hero of a role is scored on the same context pool. Legality respects bans and hero uniqueness; coverage is the share of same-role slots in which the hero was a legal replacement, with a median of 88%.

By the common reference, the strongest Tanks are The Thing (+5.0), Peni Parker (+2.3), and The Hood (+2.1), the strongest Damage heroes Magik (+4.4), Black Cat (+4.2), and Storm (+3.0), and the strongest Supports Mantis (+6.2), Rocket Raccoon (+3.9), and Ultron (+3.5). The observed-meta scores by rank third show which heroes’ values move with the environment: Elsa Bloodstone (-1.9 to +0.2), Wolverine (-1.2 to +0.6), and Mantis (+5.8 to +7.2) gain the most from the bottom to the top third, while Black Panther (+0.0 to -2.3), and Cloak & Dagger (+1.5 to -0.9) lose the most. These are pooled slopes evaluated at observed contexts, not separate rank models.

Pairs

Pair effects are reported as four-lineup contrasts on the log-odds scale: the pair’s coefficient minus the average coefficient of each member with the same-role alternatives to the other, plus the average over alternative pairs. This cancels the hero main effects and each hero’s other relationships and does not depend on where additive hero content is placed. Pairs are shown only with at least 500 identifying matches, that is, distinct development matches in which the signed feature is nonzero. Designated team-ups are labelled; the largest by contrast are Gambit with Rogue (+0.21), Iron Fist with White Fox (+0.20), and Moon Knight with Blade (+0.16). Among pairs that are not designated team-ups, the largest positive contrasts are Gambit with Deadpool (Duelist) (+0.10), Luna Snow with Daredevil (+0.06), and Black Panther with Deadpool (Vanguard) (+0.06) and the largest negative Spider-man with Angela (-0.08), Mantis with Deadpool (Strategist) (-0.07), and Hela with Iron Man (-0.06). The largest opposing matchups are The Thing over Magik (+0.11), Gambit over Angela (+0.08), Phoenix over Elsa Bloodstone (+0.07), and Cloak & Dagger over Venom (+0.07). The standard deviation of the contrasts is 0.050 across team-up-eligible pairs, 0.020 across other allied pairs, and 0.022 across opposing pairs.

A team-up-eligible pair’s coefficient combines ordinary kit complementarity, any mechanic actually used, player selection, coordination, and subsequent decisions; the data do not record activation. A

starting-matchup coefficient compares matches that begin with that configuration and includes whatever adaptation follows; it is not the effect of an opponent switching to the counter mid-match.

Stability

The bootstrap stability analysis has not been run for this fit; no stability claim is made.

Confirmation

The locked evaluation compares the candidate and the refitted headline model on the same 19,804 eligible confirmation matches. The paired log-loss improvement is +0.00184 (player-multiplicity bootstrap 95% interval +0.00151 to +0.00217), the candidate's calibration slope is 1.062 overall, and by rank third 0.908, 1.038, and 1.116. Verdict under the predeclared criterion: PROMOTE.

Table 3: Hero coefficients by lobby rank and same-slot replacement values from the selected fit

	Coefficient		Replacement, pp		Obs. meta by third					Coefficient		Replacement, pp		Obs. meta by third

Deadpool (Strategist)	-0.279	-0.026	-7.17	-6.37	-6.14	-7.15	-8.23	93											

Notes. β_h is the within-role log-odds contrast at the median lobby score of 4,548, and *slope* its change per standard deviation of lobby rank (252 points), so the coefficient at the 25th and 75th percentiles is $\beta_h \mp$ about $0.67 \times \text{slope}$. Replacement values are exact predicted probability differences in percentage points over 120,000 development matches: observed meta replaces the actual same-role incumbent, common reference compares with the average legal same-role hero in the same slot. Rank thirds are split at lobby scores 4,437 and 4,642. Coverage is the share of same-role slots where the hero was legal (not on that side already, not banned). Heroes are sorted by the common-reference score within role. Cells with fewer than 200 legal contexts are blank.

Table 4: Team-up-eligible starting pairs from the selected fit

Pair	Coef.	Contrast	Matches	Top third %	Pair	Coef.	Contrast	Matches	Top third %

Notes. Allied pairs designated as team-ups in the Season 9.5 catalogue, with at least 500 identifying matches, sorted by contrast. *Coef.* is $S_{hk}(r)$ at the median lobby rank under the uniform centering convention (each hero's allied deviations sum to zero across its partners and within each role pair). *Contrast* is the four-lineup log-odds contrast against same-role alternatives. *Matches* counts distinct development matches with a nonzero signed feature; *Top third %* is the share of those matches in the top lobby-rank third. Read as the synergy of a team-up-eligible starting pair.

Table 5: Other allied pairs: largest positive and negative contrasts

<i>Largest positive</i>					<i>Largest negative</i>				
Pair	Coef.	Contrast	Matches	Top third %	Pair	Coef.	Contrast	Matches	Top third %

Notes. A over B means A 's side wins more often when the two start on opposite sides than the two heroes' other matchups predict; the coefficient and contrast are oriented so that both are positive for A . At least 500 identifying matches. Starting matchups include whatever adaptation followed.
